

ASSIGNMENT 10: SOLUTION

E. ARNOLD, M-S. LIU, R. PRABHU & C.S. RICHARDS
THE UNIVERSITY OF CAMBRIDGE

Written in X_YL^AT_EX

THE W.I.M.

PREREQUISITES

The chapter *Spin Echo* from the *Theory Handbook*.

INTRODUCTION

Helium spin echo spectroscopy is a modern surface technique, allowing measurements of surface processes to be taken to greater depth than ever before. This tutorial will introduce how to simulate some experimental results that this technique can generate. Simulations are important for understanding the physics; they allow us to check our models, to see how well the model fits with the experimental data. We will focus on simulating the “wavelength intensity matrix” for a few systems.

THE WAVELENGTH INTENSITY MATRIX

One of the quantities that the helium spin echo technique can measure is the so-called “wavelength intensity matrix”. If this is not familiar to you, read the prerequisites to this tutorial. While the *Theory Handbook* covers this in full, we will only briefly discuss it here; a lengthy discussion is not appropriate for this document. The measured polarisation $P(\kappa_1, \kappa_2)$ in helium spin-echo spectroscopy can be related to the wavelength intensity matrix $I(\lambda_1, \lambda_2)$ by

$$P(\kappa_1, \kappa_2) \propto \iint I(\lambda_1, \lambda_2) \exp(2\pi i \kappa_1 \lambda_1 + 2\pi i \kappa_2 \lambda_2) d\lambda_1 d\lambda_2 + C,$$

where:

1. κ_1 and κ_2 are experimentally controllable parameters, proportional to the current through the machine’s coils;
2. λ_1 and λ_2 are the de Broglie wavelengths of the incident and scattered beams,
3. C is a constant term (effectively noise); this is measured separately, and removed.

The object of interest in this document is the wavelength intensity matrix $I(\lambda_1, \lambda_2)$. This is reconstructed from the Fourier transform of the measured polarisation; the techniques for processing it are introduced in the *Theory Handbook*, but we will discuss it in this document - allowing the reader to develop a useful skill set for helium spin-echo spectroscopy.

How do we make sense of the wavelength intensity matrix? It is very fortunate that we can interpret it as the relative intensity of the beam that has a wavelength of λ_1 in the first arm and λ_2 in the second arm. This interpretation allows us to quantify the matrix as the product of two distributions: first the wavelength distribution $\rho(\lambda_1)$ in the incident beam, and then the probability of the de Broglie wavelength changing from λ_1 to λ_2 during scattering $S(\lambda_1 \rightarrow \lambda_2)$, given the incident beam has a wavelength of λ_1 . Thus we can write

$$I(\lambda_1, \lambda_2) = \rho(\lambda_1) S(\lambda_1 \rightarrow \lambda_2).$$

How do we use this? Simulating both of these quantities, we can construct an estimate of the appearance of the wavelength intensity matrix. The matrix can be simultaneously plotted as a function of both the incident de Broglie wavelength λ_1 , and the scattered de Broglie wavelength λ_2 . Information from this plot can be compared to experiment. The code given with this document generates the transition function S from the energy of a mode, and then plots the wavelength intensity matrix using the same information.

The Tilted Projection Theorem

We have included this section as a reminder that the tilted projection theorem exists. It is detailed in significant detail in the *Theory Handbook*. We will use it here!

THE CODE

This assignment is accompanied by a set of code files. The use of this code is simple, using only two lines of code. We will list this code, then discuss how the program works. Run:

```
1 [lambda_i_Mat, lambda_f_Mat, wavelengthIntMat, tilt] = SEexpTools
   .calcMeasurementsParams(8, 0.5, 6, 30, 44.4);
2 [lambda_1D, lambda_axis_shifted, wavelengthInt_proj, energy,
   spectrum_in_energy] = SEexpTools.projectByTilt(lambda_i_Mat,
   lambda_f_Mat, wavelengthIntMat, tilt, 8);
```

which will prompt the program to ask for a small number of user inputs. Following the on-screen guidance, a set of figures are generated. These are:

1. A plot of each phonon mode as a function of the parallel momentum transfer from the helium-3 particle.
2. A plot of the wavelength intensity matrix that these phonon modes generate.
3. Plots of the projected wavelength intensity matrix in both the energy domain, and in the wavelength domain.

Part of the task below will be to investigate how changing the surface modes leads to a change in the projected matrix.

It is important to know what the variables used in the code above are. In order, in line 1, the arguments are:

1. The mean beam energy,
2. The beam energy full width at half maximum (FWHM),
3. The maximum energy transfer of the incident helium-3 particle,
4. The maximum angle of incidence for the helium-3 particle,
5. The total scattering angle.

All of the energies used are in meV. Varying the input parameters (along with the mean beam energy as inputted into line 2) will reveal the effect of a slightly different setup.

TASKS

In these tasks, we will individually explore how to create the wavelength intensity matrix for a small number of events. We will then discuss the tilted projection theorem.

Typical beam wavevectors for the Cambridge helium-3 spin-echo spectrometer are between 3.4 and 4.2 inverse angstroms. Assume that the wavevector for a particular setup has a mean of 4 angstroms. Assume that the standard deviation of the velocities of the particles in the beam is 3% (this is not the real value).

1. State the standard deviation for the wavevectors of the particles in the beam.
2. Calculate the range of wavelengths of the particles in the beam.
How can the wavelength of the particles in the beam be changed?
3. The helium beam is incident on a sample. Assume that, for this task, that all of the scattering events are elastic.
 - a) Consider a single particle in the beam. Upon collision, what is the emergent de Broglie wavelength of the particle? Give your answer relative to the incident wavelength.
 - b) Assume that, regardless of wavelength, the particles are equally likely to emerge in the correct direction to be detected. Suggest the form of the scattering distribution $S(\lambda_1 \rightarrow \lambda_2)$ for these events.
 - c) Plot the wavelength density matrix for this system as a colour map in 2D. Use the code file given to do this. Consider how

Figure 1 | The tilted projection axes for three features on a model wavelength intensity matrix.

to define a new mode in the correct place, along with the code that must accompany it.

4. Assume that, instead of always scattering elastically, that the scattering distribution $S(\lambda_1 \rightarrow \lambda_2)$ takes a different form. Describe how the inclusion of inelastic processes affects the shape of the wavelength intensity matrix.
5. Modify the code to simulate the wavelength intensity matrix for a mode with an energy distribution independent of momentum transfer. Produce this plot. Describe why it is likely to be an oversimplification of the system.

EXTENSIONS

Include and exclude various modes, and comment on the consequence this has on the wavelength intensity matrix. Repeat the same task for varying the system parameters. Then study the effect of varying the modes used, the system constants, and the mode constants on the tilted projection measurements.

When a spin echo measurement is made, it is done so along a tilted axis. Therefore it is important to understand how the behaviour of a scattering event affects the tilted projection of the wavelength intensity matrix!

SUMMARY

In this tutorial, you should have learned how to modify an existing piece of code that simulates the wavelength intensity matrix. You should have become more comfortable with the tilted projections produced by wavelength intensity matrices.

SOLUTIONS

THE W.I.M.: MAIN TASKS

Task 1: Question

State the standard deviation for the wavevectors of the particles in the beam.

Task 1: Solution

The wavevector of each particle in the beam is inversely proportional to its velocity. Therefore given the standard deviation in the velocities is 3%, the standard deviation in the wavevectors is also 3%.

Task 2: Question

Calculate the range of wavelengths of the particles in the beam. How can the wavelength of the particles in the beam be changed?

Task 2: Solution

Irrespective of whether the limits of 3.4 and 4.2 inverse angstroms hold as the true values for the cut-off points of the wavevectors, we will use them to model the limits of the distribution. Noting simply the wavevector to be defined as $2\pi/\lambda$, where λ is the wavelength of the particle in question, the range of the wavelengths can be calculated to be 1.5 to 1.8 angstroms.

Task 3: Question

The helium beam is incident on a sample. Assume that, for this task, that all of the scattering events are elastic.

- a) Consider a single particle in the beam. Upon collision, what is the emergent de Broglie wavelength of the particle? Give your answer relative to the incident wavelength.
- b) Assume that, regardless of wavelength, the particles are equally likely to emerge in the correct direction to be detected. Suggest the form of the scattering distribution $S(\lambda_1 \rightarrow \lambda_2)$ for these events.

- c) Plot the wavelength density matrix for this system as a colour map in 2D. Use the code file given to do this. Consider how to define a new mode in the correct place, along with the code that must accompany it.

Task 3: Solution

For the elastic event, the incoming and outgoing particles have the same de Broglie wavelength. If they did not, then there would have been an energy transfer. When interpreting this using the wavelength intensity matrix, we must consider the transition function $S(\lambda_1 \rightarrow \lambda_2)$. This is a delta function, centred on the incoming wavelength.

How do we plot the elastic feature? We must modify the code given with the tutorial to achieve what we desire it to. It is trivial to modify the small number of steps required to generate the output.

It is important not to overcomplicate this task. It is very simple. All that is needed to be changed in the code file is a small part of the function called `calcMeasurementsParams`. The code below, which can be seen as the original version in the appendices, calculates the scattering function for a particular system. A studious reading of the phonon models late in the provided class will reveal the mode denoted `SpecBroad` represents an elastic mode. Therefore it is the only mode we require to represent a scattering event!

```

1      %-----
2      %% find (dk, de) points of phonon
3      %-----
4
5      % SpecBroad is the elastic mode: include only this
        mode
6      modeModelHandle = SEexpTools.phononModel('SpecBroad'
7      );
8      modeDE_SpecBroad = modeModelHandle(dK_Mat);
9
10     % find the scattering function
11     energyMatchMat = zeros(size(dE_Mat));
12     energyMatchMat = energyMatchMat | abs(
13         modeDE_SpecBroad-dE_Mat) < 1e-1 | abs(
14         modeDE_SpecBroad+dE_Mat) < 1e-1;
15
16     beamIntensityMat = repmat(beamIntensity,size(
17         energyMatchMat,1),1);
18
19     % find the wavelength intensity matrix
20     wavelengthIntMat = energyMatchMat .*
21         beamIntensityMat;
22
23     % plot the wavelength intensity matrix as a colour
24         map
25     figure; hold on
26     pcolor(lambda_i_Mat, lambda_f_Mat,wavelengthIntMat);
27     shading flat
28     ...

```

Following through with plotting the optimal tilted measurement axis gives the figure in the margin.

Task 4: Question

Assume that, instead of always scattering elastically, that the scattering distribution $S(\lambda_1 \rightarrow \lambda_2)$ takes a different form. Describe how the inclusion of inelastic processes affects the shape of the wavelength intensity matrix.

Task 4: Solution

If the scattering distribution is no longer elastic, then it is no longer a Dirac delta function. It is now the case that the wavelength intensity matrix displays the three regions in figure 1: one elastic region, surrounded by two (or more) inelastic regions.

Task 5: Question

Modify the code to simulate the wavelength intensity matrix for a mode with an energy distribution independent of momentum transfer. Produce this plot. Describe why it is likely to be an oversimplification of the system.

Task 5: Solution

The final task is to introduce a constant energy mode. Reading the function `phononModel`, it should be evident that the mode denoted `Water0nNi2meV` is appropriate. Therefore again modifying the same section of code as in question 3, running the code below gives the figure in the margin

```

1      %-----
2      %% find (dk, de) points of phonon
3      %-----
4
5      % SpecBroad is the elastic mode: include only this
        mode
6      modeModelHandle = SEexpTools.phononModel('SpecBroad'
7      );
8      modeDE_SpecBroad = modeModelHandle(dK_Mat);
9
10     % initialise the constant energy mode
11     modeModelHandle = SEexpTools.phononModel('
12     Water0nNi2meV');
13     modewater = modeModelHandle(dK_Mat);
14
15     % find the scattering function
16     energyMatchMat = zeros(size(dE_Mat));
17     energyMatchMat = energyMatchMat | abs(
18         modeDE_SpecBroad-dE_Mat) < 1e-1 | abs(
19         modeDE_SpecBroad+dE_Mat) < 1e-1;
```

Figure 2 | The wavelength intensity matrix generated for a system where only elastic scattering events occur.

```

16     energyMatchMat = energyMatchMat | abs(modewater-
17         dE_Mat) < 1e-1 | abs(modewater+dE_Mat) < 1e-1;
18
19     beamIntensityMat = repmat(beamIntensity,size(
20         energyMatchMat,1),1);
21
22     % find the wavelength intensity matrix
23     wavelengthIntMat = energyMatchMat .*
24         beamIntensityMat;
25
26     % plot
27     figure; hold on
28     pcolor(lambda_i_Mat, lambda_f_Mat,wavelengthIntMat);
29     shading flat
30
31     ...

```

There are likely to be many modes appearing during scattering. In addition, we have only included zeroth order modes. Thus it is expected our system is an oversimplification.

Figure 3 | The wavelength intensity matrix produced when a mode with energy independent of momentum transfer is included.

APPENDICES

The files for use in this problem are listed below.

A: ENERGY2WAVEVECTOR

This takes an energy distribution, and returns the wavevectors to which it corresponds.

```
1 function [k] = energy2wavevector(E, mass)
2 % function [k] = energy2wavevector(E, mass)
3 %
4 % function to convert the energy of atoms in a helium beam to
   the associated wavevector
5 %
6 % k is in 1/Angstrom
7 % E is in meV
8 % mass is either 3 or 4 amu
9
10
11
12
13 % load in parameters
14 if ~exist('SE_amu','var'), load_chess_parameters;
15
16 % end condition
17 end
18
19
20
21 % if mass is 3 amu i.e. if particle is helium 3, then find mass
   in SI
22 if mass==3
23     m = SE_amu * 3.01603;
24
25 % if mass is 4 amu i.e. if particle is helium 4, then find mass
   in SI
26 elseif mass==4
27     m = SE_amu * 4.00260;
28
29 end
30
31
32
33 %find energy in SI
34 Ei_SI = E/1000*SE_e;
35
36 % find wavevector in SI
37 % in inverse angstroms
```

```

38 ki_SI = (2*m*Ei_SI).^0.5/SE_hbar;
39
40 % convert to inverse angstroms
41 k = ki_SI/1e10;

```

B: ENERGY2WAVELENGTH

Similarly to the above, this function takes an energy distribution, and returns the corresponding wavelengths.

```

1 % function lambda = energy2wavelength(energy,mass)
2 %
3 % function to convert energy (in meV) to wavelength (in Angstrom
4 % wavelength is returned in Angstroms
5
6
7
8
9 function lambda = energy2wavelength(energy, mass)
10
11 % h is Planck's constant
12 h = 6.62608e-34;
13
14 % e is the charge on the electron
15 e = 1.60218e-19;
16
17 %c is the speed of light
18 c = 2.99792e8;
19
20 % load in a file of constants
21 if ~exist('SE_amu','var'), load_chess_parameters;
22
23 % end condition
24 end
25
26
27
28
29 % if mass is 3 amu i.e. if particle is helium 3
30 % converts mass to kg
31 if mass==3
32     m = SE_amu * 3.01603;
33
34
35 % if mass is 4 amu i.e. if particle is helium 4
36 % converts mass to kg
37 elseif mass==4
38     m = SE_amu * 4.00260;
39
40
41 % helium only has two isotopes – anything else is not allowed
42 else
43     disp('Only masses 3 and 4 allowed')
44
45     %return nothing
46     return
47
48 % end conditions

```

```

49 end
50
51
52
53
54 % calculate the energy in SI units
55 % change from eV to joules
56 E_SI = energy ./ 1000*SE_e;
57
58 % calculate wavelength in metres
59 % this is the output
60 % multiply by e10 to produce angstrom output
61 lambda = SE_h ./ sqrt(2*m*E_SI) * 1e10;

```

C: SPIN ECHO EXPERIMENT TOOLS

This file brings together a large quantity of theory. For a given set of surface modes, it calculates, and plots, the projected wavelength intensity matrix along the optimal axis for measurement. Do not worry about understanding it line-by-line, but appreciate the output it produces using the method detailed previously.

```
